FARMERS' BULLETIN 912
UNITED STATES DEPARTMENT OF AGRICULTURE

Contribution from the Bureau of Biological Survey

E. W. NELSON, Chief

Washington, D. C.

February, 1918

Show this bulletin to a neighbor. Additional copies may be obtained free from the
Division of Publications, United States Department of Agriculture

BIRDS appeal strongly to the interests and affections of mankind. Not only do they charm by their graceful forms, harmonious colors, sprightly actions, and usually pleasing notes, but they have an even more important claim upon our esteem because of their great economic value.

Birds feed upon practically all insect pests. They are voracious, able to move freely from place to place, and exert a steady influence in keeping down the swelling tide of insect life.

For economic as well as for esthetic reasons, therefore, an effort should be made to attract and protect birds and to increase their numbers. Where proper measures of this kind have been taken an increase of several fold in the bird population has resulted, with decreased losses from depredations of injurious insects.

This bulletin is one of a series intended to describe the best methods of attracting birds in various parts of the United States, especially by providing a food supply and other accessories about the homestead. The area to which it is adapted is shown by the shaded portion of the map on page 3.

HOW TO ATTRACT BIRDS IN THE EAST CENTRAL STATES.

MEANS OF ATTRACTING BIRDS.

THE MEANS of increasing the number of birds about the home are few and simple. They comprise adequate protection and the provision of suitable nesting places, food, and water. In a series of publications, of which this bulletin relating to the East Central States (fig. 1) is one,¹ it is planned to recommend practicable methods of attracting birds about homes in the various parts of the United States. Especial attention will be given to the value of fruit-bearing shrubs and trees, as less information relating to these as a means of attracting birds is available than concerning more widely known but not more important measures, as protection, winter feeding, and the supplying of nesting boxes and water. Furthermore, the last-named measures need not vary so much with the locality as does choice of fruit-bearing shrubs and trees.

FIG. 1.—Map of the United States, the shaded area showing the territory to which this bulletin applies.

PROTECTION.

Protection is the prime requisite for increasing the number of birds in any area, and the results of protection are in direct proportion to its thoroughness. Besides being insured against every form of persecution by human kind, birds must be defended from various natural foes. The most effectual single step is to surround the pro-

¹ Bulletins already issued in the series are Farmers' Bulletins 621, relating to the Northeastern States; 760, to the Northwestern States; and 844, to the Middle Atlantic States.

posed bird sanctuary with a vermin-proof fence (fig. 2). Such a fence should prevent entrance either by digging or by climbing, but will serve its greatest use if it can not be climbed and is therefore cat-proof. For this purpose the erect part of the fence above ground should be 6 feet high, and the mesh should measure not more than $1\frac{1}{2}$ inches. The overhang should be 2 feet wide, and if strung with wires, these should be not more than $1\frac{1}{2}$ inches apart. If it is impracticable to build an impenetrable fence, the next best device is to put guards (fig. 3) of sheet metal on all nesting trees and on poles supporting bird houses. This should be done in any case where squirrels or snakes are likely to intrude, as it is usually impossible to fence out these animals. Tree guards should be 6 feet or more above ground. Attacks by hawks, owls, crows, jays, or other enemies are best controlled by eliminating the destructive individuals. Those who wish to combat English sparrows will find full directions for so doing in Farmers' Bulletin 493.¹

BREEDING PLACES.

Although a considerable number of our native birds build their nests on the ground, the majority place them in trees or shrubs, either in holes or on the limbs or in the crotches. Shrubby and trees for nesting sites, therefore, are essential for making a place attractive to birds, and a double purpose is served if the kinds planted are chosen from the list of fruit-bearing species given farther on. Shrubs should be allowed to form thickets and should be pruned back severely when young so as to produce numerous crotches.

Constant removal of old trees, and modern tree-surgery, have resulted in a great diminution in the number of tree cavities, the

FIG. 2.—Cat-proof fences: *a*, With barbed wires; *b*, with loose overhanging netting.

natural homes of most of our hole-nesting birds. Fortunately most of these birds will utilize artificial nest cavities, or bird houses. The sizes useful for various birds, plans for making, and illustrations of numerous bird boxes are given in Farmers' Bulletin 609.² Styles

¹ Dearborn, Ned, "The English Sparrow as a Pest," revised, 1917.

² Dearborn, Ned, "Bird Houses and How to Build Them," 1914.

of bird houses may be varied almost endlessly. These structures may be improvised by anyone, but they may be purchased also from numerous dealers.

The most common errors in putting out bird houses are choosing poor locations and supplying too many boxes. A bird house needs only partial shade, and houses on poles usually are taken. Martins prefer a house standing apart from trees. Entrances to boxes should be sheltered by projecting roofs and should face away from the prevailing wind and rain storms. All bird houses should be constructed so that the interior may be easily examined and cleaned.

As a rule birds do not like being crowded, and if a place is studded with bird houses only a few of them will be occupied. Birds not only do not want bird neighbors too near, but are impatient of human meddling, and therefore should have as much privacy as possible during the actual incubating and brooding. Nests built in shrubbery are especially liable to come to a bad end if the birds are disturbed frequently.

If ground-nesting birds, as bobolinks, meadowlarks, and bobwhites, are to be protected, grass in the nesting fields must not be cut during the breeding season.

FIG. 3.—Tree guards.

WATER SUPPLY.

Nothing has a more potent attraction for birds during hot weather than drinking and bathing places. The birds' water supply should be a pool not more than a few inches deep, the bottom sloping gradually upward toward the edge. Both bottom and edge should be rough, so as to afford a safe footing. A giant pottery saucer (fig. 4, *a*) is an excellent device, or the pool may be made of concrete, or even metal, if the surface be roughened (fig. 4, *b*). The bird bath may be elevated, or on the ground if in an open space where skulking enemies can not approach too near.

A water supply is appreciated in winter as well as in summer; if running water can not be provided that supplied should be warmed to delay freezing.

FOOD SUPPLY.

Food supply is the vital factor in bird life and the most important single offering that can be made in efforts to attract birds. It is im-

portant to note that an ample supply of food prior to and during the nesting season tends to increase the number of eggs laid and also the number of broods in a season. Bird food may be supplied in two ways—by planting trees, shrubs, and herbs which produce seeds or fruits relished by birds, and by exposing food in artificial devices. The most familiar phase of the latter method is winter feeding.

FIG. 4.—Bird baths: *a*, Pottery; *b*, metal or concrete.

ing between birds and human kind.

The winter foods commonly used include suet or other fat, pork rinds, bones with shreds of meat, cooked meats, meal worms, cut-up apples, birdseed, buckwheat, crackers, crumbs, coconut meat, cracked corn, broken dog-biscuits or other bread, hemp seed, millet, nut meats of all kinds (especially peanuts), whole or rolled oats, peppers, popcorn, pumpkin or squash seeds, raw or boiled rice, sunflower seeds, and wheat. The waste product of grain mills, known as screenings, is a valuable and inexpensive source of food for birds.

The methods of making these supplies available to birds are as varied as the dietary itself. A device very commonly used is the food tray (figs. 5 and 6). This may be put on a tree or pole by a

ARTIFICIAL FOOD.

During the season when the natural food supply is at its lowest ebb, birds respond most readily to our hospitality. Winter feeding has become very popular, and the result has been to bring about better understand-

FIG. 5.—Food tray.

window or at some other point about a building, or strung upon a wire or other support on which it may be run back and forth. The last device is useful in accustoming birds to feed nearer and nearer a comfortable observation point. A fault with food shelves is that wind and rain may sweep them clean and snow may cover the food. These defects may be obviated in part by adding a raised ledge about the margin or by placing the shelf in the shelter of a wall or shielding it with evergreen branches on one or more sides.

Feeding devices not affected by the weather are preferable. An excellent one is a coconut with a hole made in one end (fig. 7). The cavity is filled with

FIG. 6.—Food shelf.

FIG. 7.—Coconut larder.

chopped suet and nuts or other food mixture, and the nut is suspended by a wire from a limb. The size of the hole regulates the character of the guests; if small, large birds can not gobble the supply. The coconut meat as well as the stuffing is eaten. Cans with small openings may be substituted for coconuts. Food baskets of any desired size made of wire netting or a metal grating may be hung up or fastened to the trunk of a tree. Food mixtures in melted fat may be poured into holes made in a branch or stick (fig. 8) or in cracks of bark or over evergreen branches. All of these devices minimize or counteract the disturbing effects of stormy weather.

More elaborate apparatus for the same purpose comprises various forms of food hoppers (figs. 6 and 9) and food houses. The food

hoppers in common use for domestic fowls are adapted to the feeding of birds, and some special forms are now manufactured for wild birds.

The food house is a permanent structure, with solid roof, and glass on one or more sides to permit observations (fig. 10). The food trays it contains are entirely sheltered from the weather. In one style this result is obtained by mounting the house on a pivot and furnishing it with vanes (fig. 11), which, if large enough, keep the open side always away from the wind.

FIG. 8.—Feeding stick.

hutches or making wigwamlike shocks of corn or grain sheaves under which food may be scattered. The opening should be to the south.

Those who desire to have birds about their homes should not feel that their power to attract them is gone when winter is over. Winter feeding easily passes into summer feeding, and experience proves that some birds gladly avail themselves throughout the year of this easy mode of getting a living.

NATURAL FOOD.

We have thus far considered ways of feeding birds tidbits we ourselves have gleaned. We may feed them by another method, by cultivating their natural food plants and allowing them to reap the harvest in their own way.

Less has been done in this respect for the true seed-eating birds than for those fond of pulpy fruits. The reason is obvious—our seed-eating birds largely patronize weeds, which we do not wish to cultivate, while the fruit eaters depend upon many plants which we hold in such esteem for their ornamental value that they are generally cultivated.

FIG. 9.—Food hopper (roof detachable).

FEEDING SEED-EATING BIRDS.

Something can be done, however, to attract the seed eaters about our homes. A number of commonly cultivated annual plants, belonging to the same groups as those upon which the birds feed extensively in nature, produce good crops of seeds. These plants, being dependent upon cultivation, can be used without fear that they will become

pests. The following are suggested for the purpose: Prince's feather,¹ love-lies-bleeding,² asters, calandrinias, blessed-thistle,³ centaureas, California poppies,⁴ sunflowers, tarweed,⁵ forget-me-nots, *Polygonum orientale* and *P. sachalinense*, *Portulaca*, *Silene*, and "sugar cane" (sorghum varieties).

The various millets are relished by nearly all seed-eating birds. Common millet,⁶ Japanese millet or barnyard grass,⁷ and German millet or Hungarian grass,⁸ may be obtained from most seedsmen, and should be planted in abundance by those wishing to attract granivorous birds. The height and stiffness of stalk of varieties of sorghum should make these abundant seeders valuable in winter. Japanese millet holds its seeds well, and if planted thickly where it can grow up through a horizontal lattice work makes a valuable cover and feeding place for winter birds. Canary grass⁹ and various species of *Pennisetum* also are good for seed-eating birds.

Alders and birches bear in their numerous cones a supply of seeds which are eagerly sought for by redpolls, siskins, and goldfinches during the winter. Still another group of birds may be catered to by planting ashes and box elders. The winged fruits of these trees are opened and the seeds eaten by pine and evening grosbeaks, the visits of these birds being largely regulated by the supply of this kind of food. Larches, pines, and other conifers are attractive to crossbills as well as to some of the species just mentioned.

FIG. 10.—Food house.

FEEDING FRUIT-EATING BIRDS.

Feeding fruit-eating birds is best accomplished by planting selected species of fruit-bearing shrubs and trees. Through late spring and summer there is usually an abundance of insect food, in addition to fruit enough for all the birds. So far as fruit alone is concerned, fall is the season of overflowing abundance; in winter the supply gradually decreases, and late winter and early spring are the seasons of actual scarcity. This is the critical time of year for many birds, and a plentiful supply of wild fruit will tide them over. Fortunately, everywhere in the United States there are some fruits that persist

⁴ *Eschscholtzia*.

⁵ *Madia elegans*.

⁶ *Panicum miliaceum*.

⁷ *Echinochloa crus-galli*.

⁸ *Chætochloa italica*.

⁹ *Phalaris canariensis*.

until there is no longer and need of them. If enough are planted, no birds able to live on this class of food should starve. The best of these long persisting fruits are juniper, bayberry, thorn apples and related fruits, holly, and snowberry.

Table I shows the relative popularity with birds of important genera of fleshy fruits. From these genera and a few others have been selected the species adapted to the East Central States, that make up Table II. Various considerations have influenced choice, as ornamental value, earliness, lateness, or length of fruiting season, and especially availability of the plants through ordinary channels of trade. The data on fruiting seasons have been compiled from the principal herbaria of the East Central States, with a few additions from other sources.

The fruiting seasons indicated include the earliest and latest dates recorded for the East Central States. Hence it can not be expected that fruit will be available in any one locality throughout the entire bearing season of a plant unless a large number of plants are set out and in a variety of situations. Purchasers may obtain information from nursery catalogues as to where, when, and how to plant. Notes on species which may be substituted for some of those in the main list, and other comments, follow the table.

NOTES ON TABLE II.

- Juniper. *Juniperus horizontalis* holds its fruit as well as the others but is easily covered by snow. Yew (*Taxus canadensis*), season middle of July to middle of September, should be mentioned here. It is ornamental, furnishes bird food, and may be cultivated anywhere in this area.
- Hackberry. *Celtis mississippiensis* may be substituted in the south.
- Mulberry. *Morus alba* and *M. tatarica* also may be used.
- Pokeweed. Let it grow through shrubs or a trellis which will support it in winter.
- Strawberry. Little dealt in; must usually be transplanted from woods and fields.
- Dewberry. *Rubus triflorus* suited to wet situations, *R. canadensis* for the north, and *R. hispidus* are good substitutes.
- Rose. *Rosa setigera*, *R. virginiana* (*lucida*), and *R. carolina* may be substituted. The last is adapted to wet places.
- Chokeberry. Often called *Pyrus* or *Aronia nigra*. *P. arbutifolia*, another native species, retains its fruit just as long, but the fruit becomes very dry toward the end of the season.
- Juneberry. *Amelanchier canadensis*, sold by nurserymen, is a composite species. Several species are now recognized, among which *A. lævis* is a notably early fruiter and *A. sanguinea* a late one. Some fruit of juneberries occasionally hangs much later than the season indicated, but in very dry condition.
- Thorns. The species recommended are those usual in the trade; most others will serve as well.
- Cherry. *Prunus pumila*, a low plant of sandy areas, and *P. virginiana* also may be used.
- Sumac. *Rhus copallina* or *R. hirta* may be substituted.
- Buckthorn. The introduced *Rhamnus cathartica* may be used; it retains fruit until late spring.
- Grape. *Vitis cordifolia* may be added.
- Virginia creeper. Often listed under the names *Ampelopsis* and *Parthenocissus*. The Japanese creeper or Boston ivy (*P. tricuspidata*) is a good introduced substitute.
- Buffaloberry. *Shepherdia* (*Lepargyrea*) *argentea*, the true buffaloberry, furnishes good bird food. Other plants in this family, the oleasters (*Elæagnus longipes*, *E. angustifolia*, *E. multiflora*, *E. parviflora*, and *E. umbellata* also are good.
- Wild sarsaparilla. *Aralia racemosa* may be substituted.
- Dogwood. *Cornus alternifolia* and *C. asperifolia*, native, and *C. alba* and *C. sanguinea*, introduced, are worthy substitutes.
- Huckleberry. *Gaylussacia baccata* is often sold as *G. resinosa*.
- Blueberry. Any native species may be substituted.
- Privet. *Ligustrum acuminatum*, *L. amurense*, *L. ciliatum*, *L. ibota*, and *L. microcarpum*, all introduced, are equally good. Must not be clipped; berries borne on outer twigs.
- Snowberry. *Symphoricarpus occidentalis* is just as good.

PROTECTING CULTIVATED FRUITS.

Birds devour cultivated fruit principally because the processes of cultivation diminish the wild supply. The presence of wild fruit in a locality always serves to protect domestic varieties, especially when the wild trees or shrubs are of the same kinds as the cultivated ones and ripen earlier. Among those most useful for the purpose are mulberry, wild blackberries and strawberries, Juneberry, wild cherry, and elderberry. Species suitable for the East Central States are shown in Table III.

TABLE III—Seasons of fruits useful to protect cultivated varieties.

Common name.	Scientific name.	Native or introduced.	To protect—	Fruiting season.
